ABSTRACT

The morphological parameters such as the length, width, height and weight of 20 pairs of testes were measured in this study. The volume of the testis was calculated using the formula: Volume = length (L) × width (W) × height (H) × 0.71. These morphological parameters of the right and left testes were compared.

The total length, width and height of both testes of 41–50-years-old men were 4.53±0.46 cm, 3.05±0.31 cm and 2.58±0.36 cm respectively. The total volume and weight were 25.53±6.06 cm³ and 20.93±4.75 g respectively. The length, height, volume and weight of the right testis were significantly larger than of the left testes in 41–50-years-old men. Only the width of the right and the left testes differed statistically non-significantly.

Keywords: *men; morphological; testis; volume; weight*

INTRODUCTION

The testicular morphological parameters have been studied in recent years. The methods used for testicular volume assessment involve the use of callipers, orchidometry or ultrasonography. Orchidometry is a conventional method that has been used for many years. However, the ultrasound measurement of testicular volume is more reliable than orchidometry for patients [5, 10]. The most rigorous method for measuring of the volume of testis is the Archimedes principle of water displacement [1, 7, 9]. However, this method can be used only for dead patients or after orchiectomy. For live patients, scientists have established some formulas for determining of testicular volume [3, 6, 8, 9].

In adult males, testicular volume and weight are measured in relation to spermatogenic activity. Scientists have ascertained that the left testis is smaller than the right one [2, 4].

The aim of this study was to measure and compare the morphological parameters (length, width, height, volume and weight) of 41–50-years-old men's testes.

MATERIAL AND METHODS

The study was approved by the Kaunas Region Biomedical Research Ethics Committee (No. BE-2-1, 07.04.2015).

The pairs of testes from 20 men aged 41–50 years were obtained from the Kaunas Division of State Forensic Medicine Service after autopsy in 10% formaldehyde solution. Only testes without visible morphological pathologies were selected as suitable for this investigation. The testes were rinsed in streaming tap water and dried with blotting paper and weighed. The length, width and height of each testis were measured using sliding callipers. The volume of the testis was calculated using the formula: $\text{Volume} = \text{length (L)} \times \text{width (W)} \times \text{height (H)} \times 0.71$ [8, 9].

The Statistica program (Statistica Version 5, StatSoft inc.) was used for statistical analysis of results. The data were expressed as mean \pm standard deviation (SD), and $p < 0.05$ was taken as significant.

RESULTS

The total length of both testes of 41–50-years-old men was 4.53 ± 0.46 cm. The length of right testes differed significantly from the left (4.63 ± 0.46 cm and 4.44 ± 0.45 cm respectively, $p < 0.05$) (Figure 1).

The total width of men's both testes was 3.05 ± 0.31 cm. The width of the right testes was larger (3.08 ± 0.32 cm) than of the left (3.02 ± 0.31 cm), but the difference was statistically non-significant ($p > 0.05$) (Figure 2).

The total height of both testes in 41–50-years-old men was 2.58 ± 0.36 cm (Figure 3). The right testes were significantly higher than the left (2.68 ± 0.39 cm and 2.48 ± 0.31 cm respectively, $p < 0.05$).

Figure 4 shows that the total volume of the right and left testes in 41–50-years-old men was 25.53 ± 6.06 cm³. The right testes had larger volume than the left (27.31 ± 6.44 cm³ and 23.75 ± 5.23 cm³ respectively, $p < 0.05$).

Figure 1. The length of the testes in 41–50-years-old men.

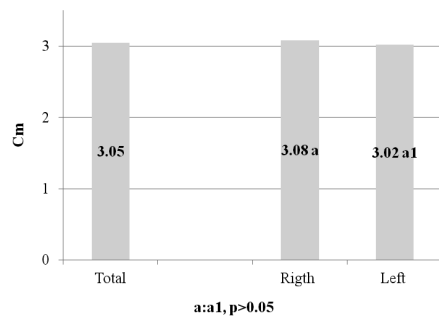

Figure 2. The width of the testes in 41–50-years-old men.

Figure 3. The height of the testes in 41–50-years-old men.

Figure 4. The volume of the testes in 41–50-years-old men.

Figure 5. The weight of the testes in 41–50-years-old men.

The weight of both testes was 20.93 ± 4.75 g. The weight of the right and the left testes differed statistically significantly (21.87 ± 4.98 g and 19.98 ± 4.44 g respectively, $p < 0.05$, Figure 5).

DISCUSSION

The peculiarities and differences of human testicular volume have been studied in recent years. Scientists have offered various formulas for determining the testicular volume: (a) for a prolate ellipsoid: volume = length \times width \times height \times 0.52; (b) for a prolate spheroid: volume = length \times width² \times 0.52; (c) the empiric formula of Lambert: volume = length \times width \times height \times 0.71, and (d) volume = length \times width \times height \times ($\pi/6$), and others [3, 6, 8, 9, 11]. Mbaeri with co-authors [8] determined that the most rigorous method for calculating of testis volume is the empiric formula of Lambert. Therefore, we used this formula in our study.

Scientists have ascertained that the right testis is larger than the left. This is true for weights of the parenchyma and the tunic as well as for the total weight and volume of the testis. The difference is about a 10% reduction in weight on the left side [4]. Our results approved that the right testes had significantly larger length, height, volume and weight in comparison with the left. Due to the smaller size of the left testis, it produces fewer spermatozoa on average than the right [2, 4, 5, 12].

CONCLUSIONS

The length, height, volume and weight of the right testis in 41–50-years-old men were significantly larger than those of the left testes. Only the width of the right and left testes differed statistically non-significantly.
