On Riemann problem in weighted Smirnov classes with general weight

BILAL BILALOV, AYSEL GULIYEVA, AND SABINA SADIGOVA

Abstract. Weighted Smirnov classes in bounded and unbounded domains are defined in this work. Nonhomogeneous Riemann problems with a measurable coefficient whose argument is a piecewise continuous function are considered in these classes. A Muckenhoupt type condition is imposed on the weight function and the orthogonality condition is found for the solvability of nonhomogeneous problem in weighted Smirnov classes, and the formula for the index of the problem is derived. Some special cases with power type weight function are also considered, and conditions on degeneration order are found.

1. Introduction

Let $\Gamma$ be some rectifiable Jordan contour on the complex plane $\mathbb{C}$ and let $X(\Gamma)$ be a Banach space of functions on $\Gamma$. Let $E^+_X(\text{int}\Gamma)$ and $E^-_X(\text{ext}\Gamma)$ be the Smirnov classes of functions analytic in $\text{int}\Gamma$ and $\text{ext}\Gamma$, respectively, generated by the metric of $X(\Gamma)$. Let $G : \Gamma \to \mathbb{C}$ and $g \in X(\Gamma)$ be some given functions. Consider the Riemann problem

$$
F^+(\tau) - G(\tau) F^-(\tau) = g(\tau), \quad \tau \in \Gamma,
$$

where $F^+(\tau)$ ($F^-(\tau)$) means the nontangential boundary value of the function $F^+ \in E^+_X(\text{int}\Gamma)$ ($F^- \in E^-_X(\text{ext}\Gamma)$) at a point $\tau \in \Gamma$ from the inside $\Gamma$ (from the outside $\Gamma$). Here $G(\cdot)$ is called the coefficient, and $g(\cdot)$ the right-hand side of problem (1). This problem has a deep history and is well studied in different formulations. Monographs of various mathematicians are devoted to this direction (see, for example, [10, 13, 15, 20, 28, 29, 30]). $L^p$-theory was developed in the monograph [10]. The case of a weighted
Lebesgue space with power weight was considered in [16, 17, 23, 24, 25, 27]. Namely, the general solution of the homogeneous Riemann problem with a piecewise-continuous coefficient in the Smirnov weight classes with a weight of the general form is constructed in the papers [23, 24, 27]. In [27], a general solution to the nonhomogeneous Riemann problem with a piecewise continuous coefficient in the weighted Smirnov classes with the weight of a power form is found. In paper [25], nonhomogeneous Riemann problem with a piecewise Hölder coefficient is considered, and a particular solution to this problem is found in Smirnov weight classes with a general weight. The Riemann problems associated with the metrics of the Lebesgue space with a variable exponent of summability and Morrey spaces were studied in [7, 8, 14, 21]. In [1]–[6], the Riemann problem is used to study the basic properties of special systems of functions in Lebesgue spaces. It should be noted that in all these works, strong restrictions are imposed on jumps of the argument of the coefficient of the problem and on the weight function.

Weighted Smirnov classes in bounded and unbounded domains are defined in this work. Nonhomogeneous Riemann problems with a measurable coefficient whose argument is a piecewise continuous function are considered in these classes. A Muckenhoupt type condition is imposed on the weight function and the orthogonality condition is found for the solvability of nonhomogeneous problem in weighted Smirnov classes, and the formula for the index of the problem is derived. Some special cases with power type weight function are also considered, and conditions on degeneration order are found.

It should be noted that problems close to the topic of this article are considered in works [31, 32] and the weighted Hardy classes (we call them weighted Smirnov classes) are defined in a different way and impose more restrictive conditions on the weight function. Analogues of classical results are established in these classes.

2. Necessary information and auxiliary facts

In this section, we state some notations and facts to be used to obtain our results. By $O_r(z_0)$ we denote a circle of radius $r$ centered at $z_0$ on the complex plane $\mathbb{C}$, i.e., $O_r(z_0) \equiv \{z \in \mathbb{C} : |z - z_0| < r\}$. $|M|$ means the Lebesgue (linear) measure of the set $M \subset \Gamma$, where $\Gamma \subset \mathbb{C}$ is some rectifiable curve. By $\overline{n,m}$ we denote the set $\{n, n + 1, \ldots, m\}$, and $[x]$ means the integer part of a number $x \in \mathbb{R}$. Notation $f(x) \sim g(x)$, $x \in M$, means that there exists $\delta > 0$ with

$$0 < \delta \leq \frac{|f(x)|}{|g(x)|} \leq \delta^{-1}, \quad x \in M.$$

Let us give a definition for Carleson curve.
Definition 1. A Jordan rectifiable curve $\Gamma$ on the complex plane is called a Carleson curve or a regular curve if
\[
\sup_{z \in \Gamma} |\Gamma \cap O_r(z)| \leq cr, \quad r > 0,
\]
where $c$ is a constant independent of $r$.

For more information about this concept see, e.g., [11, 12].

Let $\Gamma$ be some Jordan rectifiable curve and $\omega (\cdot)$ be a weight function on $\Gamma$, i.e., $\omega (\xi) > 0$ for a.e. $\xi \in \Gamma$.

Definition 2. We will say that the weight function $\omega : \Gamma \to \mathbb{R}^+ = (0, +\infty)$ belongs to the Muckenhoupt class $A_p (\Gamma)$ ($p > 1$), if
\[
\sup_{z \in \Gamma} \sup_{r > 0} \left( \frac{1}{r} \int_{\Gamma \cap O_r(z)} |\omega (\xi) | \, |d\xi| \right)^{\frac{1}{p-1}} < +\infty.
\]

We will need some facts about the weights $\omega (\cdot)$, which satisfy the Muckenhoupt condition $A_p (\Gamma)$, $1 < p < +\infty$, on the rectifiable curve $\Gamma$. The following statement is true.

Statement 1. i) If $\omega \in A_p (\Gamma)$, $1 < p < +\infty$, then $\omega \in A_q (\Gamma)$ for $q > p$; ii) $\omega \in A_p (\Gamma)$, $1 < p < +\infty$, if and only if $\omega^{-\frac{1}{p'}} \in A_{p'} (\Gamma)$, $\frac{1}{p} + \frac{1}{p'} = 1$; iii) if $\omega \in A_p (\Gamma)$, $1 < p < +\infty$, then $\omega \in A_q (\Gamma)$ for some $q$ with $1 < q < p$.

We will also use the following statement by Coifman and Fefferman [9].

Statement 2. If the function $\omega (\cdot) > 0$ satisfies the Muckenhoupt condition $A_p (\Gamma)$, $1 < p < +\infty$, then for sufficiently small $\delta > 0$ the “inverse Hölder inequality”
\[
\left( \frac{1}{r} \int_{\Gamma \cap O_r(z)} |\omega (\xi) |^{1+\delta} \, |d\xi| \right)^{\frac{1+\delta}{1+2\delta}} \leq c \left( \frac{1}{r} \int_{\Gamma \cap O_r(z)} \omega (\xi) \, |d\xi| \right)^{1+\delta}, \quad r > 0, \ z \in \Gamma,
\]
holds, where $c = c(\delta)$ is a constant independent of $r$ and $z \in \Gamma$.

As usual, by $L_{p,\omega} (\Gamma)$ we denote the weighted Lebesgue space of functions endowed with the norm
\[
\|f\|_{L_{p,\omega} (\Gamma)} = \left( \int_{\Gamma} |f (\xi)|^p \omega (\xi) \, |d\xi| \right)^{\frac{1}{p}}.
\]
Consider the singular Cauchy operator
\[
S_\Gamma (f) = \frac{1}{2\pi i} \int_{\Gamma} \frac{f (\xi)}{\xi - \tau} \, d\xi, \quad \tau \in \Gamma.
\]
The following theorem is valid.
Theorem D. The operator $S_{\Gamma}$ is bounded in $L_p(\Gamma)$, $1 < p < +\infty$, only when $\Gamma$ is a regular curve. Moreover, if $\Gamma$ is a regular curve, then the singular operator $S_{\Gamma}$ is bounded in $L_{p,\omega}(\Gamma)$, $1 < p < +\infty$, only when $\omega \in A_p(\Gamma)$.

For more information about these results see, e.g., [11, 12]. We will also use the following result.

Privalov theorem. The following statements hold true: i) the singular operator
\[ S_{\Gamma}f(z) = \frac{1}{2\pi i} \int_{\Gamma} \frac{f(\xi)}{\xi - z} d\xi, \quad z \in \Gamma, \]
acts and is bounded in the space $\text{Lip}_\alpha(\Gamma)$, if $\Gamma$ is a piecewise smooth curve with no cusps; ii) the same statement remains true when $\Gamma$ is a Radon curve with no cusps.

Recall that the Lipschitz space $\text{Lip}_\alpha(\Gamma)$ is a Banach space on $\Gamma$ with the norm
\[ \|f\|_{\text{Lip}_\alpha(\Gamma)} = \max_{z \in \Gamma} |f(z)| + \sup_{z_1, z_2 \in \Gamma} \frac{|f(z_1) - f(z_2)|}{|z_1 - z_2|^\alpha}. \]
For more information about this result see, e.g., [10] and [22].

Let $G(\xi) = |G(\xi)| e^{i\theta(\xi)}$ be complex-valued functions on the curve $\Gamma$. We make the following basic assumptions on the coefficient $G(\cdot)$ of the considered boundary value problem and $\Gamma$:

(i) $|G(\cdot)|^{\pm 1} \in L_\infty(\Gamma)$;
(ii) $\theta(\cdot)$ is piecewise continuous on $\Gamma$, and $\{ \xi_k : k \in [1, r] \} \subset \Gamma$ are discontinuity points of the function $\theta(\cdot)$;
(iii) $\Gamma$ is either Lyapunov or Radon curve (i.e., it is a limited rotation curve) with no cusps. Direction along $\Gamma$ will be considered as positive, i.e., when moving along this direction the domain $D$ stays on the left side. Let $a \in \Gamma$ be an initial (and also a final) point of the curve $\Gamma$. We will assume that $\xi \in \Gamma$ follows the point $\tau \in \Gamma$, i.e. $\tau \prec \xi$, if $\xi$ follows $\tau$ when moving along a positive direction on $\Gamma \setminus a$, where $a \in \Gamma$ represents two stuck points $a^+ = a^-$, with $a^+$ a beginning, and $a^-$ an end of the curve $\Gamma$.

So, without loss of generality, we will assume that $a^+ \prec \xi_1 \prec \cdots \prec \xi_r \prec b = a^-$. Denote one-sided limits $\lim_{\xi \to \xi_0, \xi \in \Gamma} g(\xi)$ of the function $g(\xi)$ at the point $\xi_0 \in \Gamma$ generated by this order by $g(\xi_0 \pm 0)$, respectively. The jumps of the function $\theta(\xi)$ at the points $\xi_k$, $k \in [1, r]$, are denoted by $h_k: h_k = \theta(\xi_k + 0) - \theta(\xi_k - 0)$, $k \in [1, r]$.

Let $D^+ \subset \mathbb{C}$ be a bounded domain with the boundary $\Gamma = \partial D^+$, which satisfies the condition (iii). Denote by $E_p(D^+)$, $1 < p < \infty$, a Smirnov Banach space of analytic functions in $D^+$ with the norm
\[ \|f\|_{E_p(D^+)} = \|f^+\|_{L_p(\Gamma)}, \quad f \in E_p(D^+), \]
where $f^+ = f/\Gamma$ are non-tangential boundary values of the function $f$ on $\Gamma$.

Based on the norm (2), we define the weighted Smirnov class. Let $\rho \in L_1(\Gamma)$ be some weight function. Define weighted Smirnov class $E_{p,\rho}(D^+)$ by

$$E_{p,\rho}(D^+) \equiv \left\{ f \in E_1(D^+) : \|f^+\|_{L_p,\rho(\Gamma)} < +\infty \right\}.$$ 

Let

$$\|f\|_{E_{p,\rho}(D^+)} = \|f^+\|_{L_p,\rho(\Gamma)}.$$ 

Similarly we define the Smirnov classes in an unbounded domain. Let $D^- \subset \mathbb{C}$ be an unbounded domain containing infinitely remote point ($\infty$).

Denote by $mE_1(D^-)$ a class of functions from $E_1(D^-)$ which are analytic in $D^-$ and have an order $k \leq m$ at infinity, i.e., the function $f \in E_1(D^-)$ has a Laurent decomposition $f(z) = \sum_{k=-\infty}^m a_k z^k$ in the vicinity of the infinitely remote point $z = \infty$, where $m$ is some integer.

For a given weight function $\rho \in L_1(\Gamma)$, the weighted class $mE_{p,\rho}(D^-)$ is defined as

$$mE_{p,\rho}(D^-) \equiv \left\{ f \in mE_1(D^-) : \|f^-\|_{L_p,\rho(\Gamma)} \right\}$$ 

with

$$\|f\|_{mE_{p,\rho}(D^-)} = \|f^-\|_{L_p,\rho(\Gamma)},$$

where $f^-$ are non-tangential boundary values of the function $f$ on $\Gamma$.

We will also use some results of [23, 24, 25, 27] related to the solvability of homogeneous and nonhomogeneous Riemann problem in weighted Smirnov classes. Consider the following homogeneous Riemann problem in weighted Smirnov classes:

$$F^+(\xi) - G(\xi) F^-(\xi) = 0, \ a.e. \ \xi \in \Gamma. \quad (3)$$

By the solution of the problem (3) we mean a pair of analytic functions

$$(F^+; F^-) \in E_{p,\rho}(D^+) \times mE_{p,\rho}(D^-),$$

whose non-tangential boundary values $F^\pm(\xi)$ satisfy the equality (3) a.e. on $\Gamma$. In weightless case, this problem has been well enough studied in the monograph by Danilyuk [10].

In construction of a general solution of homogeneous Riemann problem, an important role is played by the following lemma of uniqueness of the solution for a simplest homogeneous problem.

**Lemma C** (see [10]). Assume that $D^+$ is an arbitrary domain bounded by the rectifiable curve $\Gamma$. A homogeneous problem

$$\Phi^+(\xi) - \Phi^-(\xi) = 0, \ \xi \in \Gamma,$$

in a class of functions $\Phi(\cdot)$, belonging to Smirnov classes $E_1(D^+) \ (D^- = \mathbb{C} \setminus D^+)$ and having a finite order $k$ at infinity, admits only trivial solutions in the form of polynomials, whose degree does not exceed $k$. 
Let $S$ be a length of the curve $\Gamma$ and let $z = z(s), \ 0 \leq s \leq S$, be a parametric representation of $\Gamma$ with respect to the length of the arc $s$. Rewrite the problem (3) as follows:

$$F^+ [z(s)] - G(z(s)) F^- [z(s)] = 0, \ \text{a.e.} \ s \in [0, S].$$

Let $\Omega(s) \equiv \theta(z(s)), \ 0 \leq s \leq S$, and suppose

$$h_k = \Omega(s_k + 0) - \Omega(s_k - 0), \ k \in \mathbb{N}, \ h_0 = \Omega(+0) - \Omega(S - 0),$$

where $\xi_k = z(s_k), \ 0 < s_k < S$, and $a = z(0) = z(S)$ are discontinuity points of the argument $\Omega(\cdot)$. Consider the piecewise holomorphic functions

$$Z_{(1)}(z) = \exp\left\{ \frac{1}{2\pi i} \int_{\Gamma} \ln |G(z(s))| \frac{dz(s)}{z(s) - z} \right\},$$

$$Z_{\theta}(z) = \exp\left\{ \frac{1}{2\pi i} \int_{\Gamma} \frac{dz(s)}{z(s) - z} \right\} = \exp\left\{ \frac{1}{2\pi} \int_{\Gamma} \frac{\theta(z(s))}{z(s) - z} \right\}, \ z \notin \Gamma.$$
It was proved in [10] that the following inclusion is true:

\[ \tilde{Z}_{(2)}^+(s) = |z(s) - z(0)|^{\frac{h_0^{(1)}}{2\pi}} |Z_{(2)}^+ [z(s)]|^{\frac{1}{2}} \in L_q(\Gamma), \quad q \in (0, +\infty). \]

The modulus of boundary values of the function \( Z_{(3)}(\cdot) \) can be represented by

\[ |Z_{(3)}^+ [z(\sigma)]| \equiv |z(0) - z(\sigma)|^{-\frac{h_0^{(1)}}{2\pi}} \prod_{0<s_k<S} |z(s_k) - z(\sigma)|^{-\frac{h_k}{2\pi}}, \quad (4) \]

which follows directly from the lemma below.

**Lemma 2** (see [10]). Let the curve \( \Gamma \) satisfy the condition (iii) and let \( \Omega_1(s) \) be an arbitrary jump function with the jumps \( h_0^{(1)} = \Omega_1(+0) - \Omega_1(S-0) \) at the point \( z(0) \). Then the modulus of boundary values of the function \( Z_{(3)}(\cdot) \) can be represented by the formula (4) for a.e. \( \sigma \in [0, S] \).

Let us introduce the weight function

\[ \sigma(s) \equiv |z(0) - z(s)|^{-\frac{h_0^{(1)}}{2\pi}} \prod_{0<s_k<S} |z(s_k) - z(s)|^{-\frac{h_k}{2\pi}}. \]

Let \( \rho : \Gamma \to (0, +\infty) \) be some weight function. Assume that there exist \( p_1, p_2 \in (1, +\infty) \) such that

\[ \int_0^S \sigma^{p_1}(s) \rho^{p_1}(z(s)) \, ds < +\infty. \quad (5) \]

\[ \int_0^S \sigma^{-q p_2}(s) \rho^{-q p_2}(z(s)) \, ds < +\infty, \quad (6) \]

The following theorem is true.

**Theorem 1** (see [23, 27]). Let the conditions (i)–(iii) hold for complex-valued functions \( G(\cdot) \) and the curve \( \Gamma \). Assume that the conditions (5) and (6) are satisfied for the weight function \( \rho(\cdot) \). Then the general solution of the homogeneous problem (3) in the classes \( E_{p,\rho}(D^+) \times_m E_{p,\rho}(D^-) \) has a representation

\[ F(z) = Z_{\theta}(z) P_m(z), \]

where \( Z_{\theta}(\cdot) \) is a canonical solution corresponding to the argument \( \theta(\cdot) \), and \( P_m(\cdot) \) is an arbitrary polynomial of degree \( k \leq m \) (for \( m \leq -1 \) we assume \( P_m(z) \equiv 0 \)).

This theorem has the following direct corollary.

**Corollary 1.** Let all the conditions of Theorem 1 be satisfied. Then, if \( F(\infty) = 0 \), the problem (3) has only a trivial solution in the classes \( E_{p,\rho}(D^+) \times_m E_{p,\rho}(D^-) \), i.e., when \( m \leq -1 \), the problem (3) has only a trivial solution in the classes \( E_{p,\rho}(D^+) \times_m E_{p,\rho}(D^-) \).
Consider the following nonhomogeneous Riemann problem:

\[ F^+ (z(s)) - G(z(s)) F^- (z(s)) = g(z(s)) \quad s \in (0, S), \]

where \( g \) is a given function. By the solution of the problem (7) we mean a pair of functions

\[ (F^+ (z); F^- (z)) \in E_{p,\rho} (D^+) \times_m E_{p,\rho} (D^-), \]

whose boundary values \( F^\pm \) on \( \Gamma \) a.e. satisfy (7). Introduce the weight function

\[ \nu (s) =: \sigma^p (s) \rho (z(s)), \quad s \in (0, S). \]

We will assume that the weight function \( \rho (\cdot) \) satisfies the condition

\[ \int_{\Gamma} \rho^{-\frac{2}{p}} (z(s)) |dz (s)| < +\infty. \]

The following theorem is proved in [25].

**Theorem 2.** Let the coefficients \( G(z(s)), \ 0 \leq s \leq S, \) of the problem (7) satisfy the conditions (i) and (ii). Assume that their arguments are piecewise Hölder functions and the curve \( \Gamma = z ([0, S]) \) satisfies the condition (iii). If the weight function \( \nu (\cdot) \) belongs to the Muckenhoupt class \( A_p (\Gamma), \ 1 < p < +\infty, \) and the weight function \( \rho (\cdot) \) satisfies the condition (9), then the analytic function

\[ F_1 (z) = Z_\theta (z) P_m (z) + F_1 (z), \]

is a particular solution of the nonhomogeneous Riemann problem (7) in weighted Smirnov classes \( E_{p,\rho} (D^+) \times_m E_{p,\rho} (D^-). \)

Using this theorem, the following theorem is established in [26].

**Theorem 3.** Let the coefficients \( G(z(s)), \ 0 \leq s \leq S, \) of the nonhomogeneous problem (7) satisfy the conditions (i) and (ii). Let \( \arg G(\cdot) \) be a piecewise Hölder function on \( \Gamma, \) where the curve \( \Gamma = z ([0, S]) \) satisfies the condition (iii). Assume that the weight function \( \nu (\cdot) \) defined by (8) belongs to the Muckenhoupt class \( A_p (\Gamma), \ 1 < p < +\infty, \) and the condition (9) holds, i.e., \( \rho^{-\frac{2}{p}} \in L_1 (\Gamma). \) Then the following assertions are true with regard to the solvability of the problem (7) in the classes \( E_{p,\rho} (D^+) \times_m E_{p,\rho} (D^-): \)

1) for \( m \geq -1, \) the problem (7) has a general solution of the form

\[ F(z) = Z_\theta (z) P_m (z) + F_1 (z), \]

where \( Z_\theta (\cdot) \) is a canonical solution of the corresponding homogeneous problem (3), \( P_m(z) \) is an arbitrary polynomial of degree \( k \leq m \) (for \( m = -1 \) we assume \( P_m (z) \equiv 0), \) and \( F_1 (\cdot) \) is a particular solution of the nonhomogeneous problem (7) of the form (10).
2) for \( m < -1 \), the nonhomogeneous problem (7) is solvable only when
the right-hand side \( g(\cdot) \) satisfies the orthogonality conditions
\[
\int_\Gamma g(\xi) Z_{\theta_k}(\xi) e^{k-1}d\xi = 0, \quad k \in \mathbb{Z}, m - 1,
\]
and the unique solution \( F(z) = F_1(z) \) is defined by (10).

3. Main results

3.1. Power weight. In Theorems 1 and 3, strong restrictions are imposed
on the coefficient \( G(\cdot) \) and on the weight function. In this section we consider
a more general case. First, we consider the case when the weight has a power
form. The index of the problem is found. Then a certain class of weights
is introduced, depending on the coefficient. The index of the problem is
calculated also in the case when the weight has a general form.

Let us first consider the case where the weight \( \rho(\cdot) \) has a power form
\[
\rho(s) = \prod_{k=0}^{m_0} |z(s) - z(t_k)|^{\alpha_k}, \quad s \in [0,S], \quad t_0 = 0.
\]  
(11)

Let the following relation hold:
\[
\frac{\beta_i}{p} \notin \mathbb{Z}_p \equiv \left\{ k - \frac{1}{p} : k \in \mathbb{Z} \right\}, \quad i \in \mathbb{Z}_{\geq 0},
\]  
(12)
where the numbers \( \beta_k \) are defined by
\[
\beta_k = -\frac{p}{2\pi} \sum_{i=0}^{r} h_i \chi_{T_k}(s_i) + \sum_{i=0}^{m_0} \alpha_i \chi_{T_k}(t_i), \quad k \in \mathbb{Z}_{\geq 0},
\]  
(13)
Without loss of generality, we assume \( 0 = \sigma_0 < \sigma_1 < \ldots < \sigma_l < S \),
where
\[
\left\{ \sigma_k \right\}_0 \equiv \left\{ s_k \right\}_0 \cup \left\{ t_k \right\}_0,
\]  
\( h_k = h(\sigma_k) = \theta(z(\sigma_k+0)) - \theta(z(\sigma_k-0)), \quad k \in \mathbb{Z}, \]\( h_0 = h(\sigma_0) = \theta(z(S-0)) - \theta(z(+0)) \),
are the jumps corresponding to the argument \( \theta(\cdot) \) at the points \( \sigma_k, k \in \mathbb{Z} \).
Introduce the function
\[
\tilde{\theta}(z(s)) = \begin{cases} 
\theta(z(s)), & 0 < s < \sigma_1, \\
\theta(z(s)) + 2\pi n_1, & \sigma_1 < s < \sigma_2, \\
\vdots \\
\theta(z(s)) + 2\pi n_l, & \sigma_l < s < S,
\end{cases}
\]
where \( \{n_k\}_1 \subset \mathbb{Z} \). It is not difficult to see that
\[
e^{\tilde{\theta}(z(s))} \equiv e^{i\theta(z(s))}, \quad s \notin \left\{ \sigma_k : k \in \mathbb{Z}, \right\}.
\]
We have
\[ h(\sigma_k) = \begin{cases} h_i, & \sigma_k = s_i, \\ 0, & \sigma_k \notin \{s_i\}_1^r, \end{cases} \]
\[ h(\sigma_0) = h_0. \]

Let
\[ \tilde{G}(z(s)) = |G(z(s))| e^{\tilde{\theta}(z(s))}, \quad 0 < s < S, \]
and consider the Riemann boundary value problem
\[ F^+(z(s)) - \tilde{G}(z(s)) F^-(z(s)) = g(z(s)), \quad s \in (0, S), \tag{14} \]
with the coefficient \( \tilde{G}(\cdot). \) As \( G(z(s)) \equiv \tilde{G}(z(s)), s \in (0, S), \) it is clear that the issues related to the solvability of the problems (7) and (14) in the classes \( E_{p,\rho}(D^+) \times m E_{p,\rho}(D^-) \) are equivalent to each other. It is not difficult to see that for the problem (14) the relation (13) becomes
\[ \beta_k = -\frac{p}{2\pi} \tilde{h}_k + \sum_{i=0}^{m_0} \alpha_i \chi_{T_k}(t_i), \quad k \in 0, l, \]
where \( \tilde{h}_k \) is a jump of the function \( \tilde{\theta}(z(s)) \) at discontinuity point \( s = \sigma_k, \)
i.e.,
\[ \tilde{h}_k = \tilde{\theta}(z(\sigma_k + 0)) - \tilde{\theta}(z(\sigma_k - 0)), \quad k \in 1, l. \]

We have
\[ \tilde{h}_1 = h(\sigma_1) + 2\pi n_1; \quad \tilde{h}_k = h(\sigma_k) + 2\pi (n_k - n_{k-1}), \quad k \in 2, l; \]
\[ \tilde{h}_0 = h(\sigma_0) - 2\pi n_l. \]

Considering these relations for \( \tilde{\beta}_k, \) we obtain
\[ \tilde{\beta}_1 = \beta_1 - pn_l; \quad \tilde{\beta}_k = \beta_k - p(n_k - n_{k-1}), \quad k \in 2, l; \quad \tilde{\beta}_0 = \beta_0 + pn_l. \]

Consequently,
\[ \frac{-\tilde{\beta}_1}{p} = \frac{-\beta_1}{p} + n_1; \quad \frac{-\tilde{\beta}_k}{p} = \frac{-\beta_k}{p} + n_k - n_{k-1}, \quad k \in 2, l; \]
\[ \frac{-\tilde{\beta}_0}{p} = \frac{-\beta_0}{p} - n_l. \]

Now let us define the integers \( n_k, k \in 1, l, \) from the inequalities
\[ \left\{ \begin{array}{l} -\frac{1}{q} \leq -\frac{\beta_k}{p} + n_1 < \frac{1}{p}, \\
\quad \frac{1}{q} \leq -\frac{\beta_k}{p} + n_k - n_{k-1} < \frac{1}{p}, \quad k \in 2, l. \end{array} \right\} \tag{15} \]

From the conditions \( \left\{ \frac{\beta_k}{p} \right\}_1^l \cap \mathbb{Z}_p = \emptyset \) it follows that the integers \( n_k, k \in 1, l, \)
are defined uniquely by (15). Applying Theorem 3 to the problem (14), we arrive at the following statement.
Statement 3. Let the coefficient $G(\cdot)$ and the curve $\Gamma$ satisfy the conditions (i)–(iii), the weight function $\rho(\cdot)$ is defined by (11), and $\{\beta_k\}_{0}^{l}$ is defined by (13). Assume that $\{\beta_k\}_{0}^{l} \cap \mathbb{Z}_p = \emptyset$ and the integers $n_k$, $k \in \mathbb{N}$, are defined by (15). If the conditions

$$-\frac{1}{q} < -\frac{\beta_0}{p} - n_l < \frac{1}{p}; \quad \alpha_k < \frac{p}{q}, \quad k \in \mathbb{N}, m_0, \quad (16)$$

hold, then the assertions 1) and 2) of Theorem 3 are true with regard to the solvability of the problem (7) in the classes $E_{p,\rho}(D^+) \times mE_{p,\rho}(D^-)$.

Now we consider the case, where $\beta_0$ may not satisfy (16). So let us assume that the coefficient $G(\cdot)$ and the curve $\Gamma$ satisfy all the conditions of Statement 3 except (16). The number $\beta_0$, corresponding to the function $\theta(\cdot)$, has the form

$$\beta_0 = -\frac{p}{2\pi}h_0 + \alpha_0 = -\frac{p}{2\pi}(\theta(a+0) - \theta(a-0)) + \alpha_0 = -\frac{p}{2\pi}(\theta(z(+0)) - \theta(z(S-0))) + \alpha_0.$$  

Let $z_0 \in D^+$ be an arbitrary fixed point. Consider the following analytic function in $D^-$:

$$\omega(z) = (z - z_0)\phi, \quad z \in D^-,$$

where $\phi \in \mathbb{Z}$ is some integer. We have $\omega^{-}(\xi) = (\xi - z_0)\phi$, $\xi \in \Gamma$. Let

$$\gamma(\xi) = \arg \omega^{-}(\xi), \quad \xi \in \Gamma,$$

and

$$G_1(\xi) = \tilde{G}(\xi) \omega^{-}(\xi), \quad \xi \in \Gamma.$$  

It is not difficult to see that the function $G_1(\cdot)$ satisfies the conditions (i) and (ii). We have

$$\theta_1(\xi) = \arg G_1(\xi) = \tilde{\theta}(\xi) + \gamma(\xi), \quad \xi \in \Gamma.$$  

It is absolutely clear that the discontinuity points and the jumps of the function $\theta_1(z(\cdot))$ coincide with the discontinuity points and the jumps of the function $\tilde{\theta}(z(\cdot))$ on $(0, S)$. The jump $h_0(\theta_1)$ of the function $\theta_1(\cdot)$ at the point $\xi = a = z(0) = z(S)$ is equal to

$$h_0(\theta_1) = \theta_1(z(+0)) - \theta_1(z(S-0)) = \tilde{\theta}(z(+0)) - \tilde{\theta}(z(S-0)) + \gamma(z(+0)) - \gamma(z(S-0)) = \tilde{h}_0 - 2\pi\phi.$$  

It is obvious that the quantity $h_0(\theta_1)$ does not depend on the choice of the point $z_0 \in D^+$. The quantities $\beta_k^{(1)}$, defined by (13) with regard to the coefficient $G_1(\cdot)$, are equal to

$$\beta_k^{(1)} = \tilde{\beta}_k, \quad k = 1, l; \quad \beta_0^{(1)} = -\frac{p}{2\pi}h_0(\theta_1) = -\frac{p}{2\pi}\tilde{h}_0 + p\phi = \tilde{\beta}_0 + p\phi.$$
Consequently
\[
-\frac{\beta_0^{(1)}}{p} = -\tilde{\beta}_0 - \phi = -\frac{\beta_0}{p} - n_l - \phi.
\]
Now define the number \( \phi \in \mathbb{Z} \) from the condition
\[
-\frac{1}{q} < -\frac{\beta_0^{(1)}}{p} < \frac{1}{p},
\]
i.e., set
\[
\phi = \left[ -\frac{\beta_0}{p} + \frac{1}{q} - n_l \right].
\]
Then we obtain that the coefficient \( G_1 (\cdot) \) satisfies all the conditions of Statement 3, and therefore all the conditions of Theorem 3. Modify the problem (7) in the following way:
\[
F^+ (\xi) - G (\xi) \omega^-(\xi) \frac{F^-(\xi)}{\omega^-(\xi)} = g (\xi), \quad \xi \in \Gamma,
\]
or
\[
\Phi^+ (\xi) - G_1 (\xi) \Phi^- (\xi) = g (\xi), \quad \xi \in \Gamma,
\]
where
\[
\Phi (z) = \begin{cases} 
F (z), & z \in D^+, \\
\frac{F(z)}{\omega(z)}, & z \in D^-.
\end{cases}
\]
It is absolutely clear that
\[
\Phi^- (\xi) \sim F^- (\xi) \omega^{-1} (\xi), \quad \xi \in \Gamma.
\]
Moreover, if \( F (z) \) has an expansion in a neighborhood of \( z = \infty \) of the form
\[
F (z) = \sum_{k=-\infty}^{m} a_k z^k, a_m \neq 0, \quad z \to \infty,
\]
then \( \Phi (z) \) has an expansion of the form
\[
\Phi (z) = \sum_{k=-\infty}^{m-\phi} b_k z^k, b_{m-\phi} \neq 0, \quad z \to \infty.
\]
It follows directly from these relations that the function \( F (\cdot) \) belongs to the class \( m E_{p,\rho} (D^-) \) if and only if the function \( \Phi (\cdot) \) belongs to the class \( m-\phi E_{p,\rho} (D^-) \), i.e., if the relation
\[
F(\cdot) \in_m E_{p,q}(D^-) \Leftrightarrow \Phi(\cdot) \in m-\phi E_{p,q}(D^-),
\]
holds.
Thus, the solvability of the problem (7) in the classes \( E_{p,\rho} (D^+) \times m E_{p,\rho} (D^-) \) is equivalent to the solvability of the problem (17) in the classes \( E_{p,\rho} (D^+) \times m-\phi E_{p,\rho} (D^-) \). As all the conditions of Theorem 3 are satisfied with regard to the problem (17), applying this theorem we obtain the following result.
Statement 4. Let the coefficient $G(\cdot)$ and the curve $\Gamma$ satisfy the conditions (i)-(iii), and let the weight function $\rho(\cdot)$ be defined by (11). Assume that $\beta_k, \, k \in \overline{0,l}$, defined by (13) satisfy the condition $\{\beta_k\}_{0}^{l} \cap \mathbb{Z}_p = \emptyset$, and $\alpha_k < \frac{p}{q}, \, k \in \overline{1,m_0}$. Let $\phi = \left[\frac{-\alpha_k}{p} + \frac{1}{q} - 2\left\{ \frac{\beta_k}{p} + \frac{1}{p} \right\} \right]$, where the integer $n_l$ is defined from the inequalities (15). Then the following assertions are true with regard to the solvability of the problem (17) in the classes $E_{p,\rho}(D^+) \times_{m-\phi} E_{p,\rho}(D^-)$:

(1) for $m-\phi \geq -1$, the problem (17) has a general solution of the form

$$
\Phi(z) = Z_{\theta_{1}}(z) P_{m-\phi}(z) + \Phi_{1}(z),
$$

where $Z_{\theta_{1}}(\cdot)$ is a canonical solution of the homogeneous problem with the coefficient $G_{1}(\cdot)$, $P_{m-\phi}(\cdot)$ is an arbitrary polynomial of degree $k \leq m-\phi$ (for $m-\phi = -1$ we assume $P_{m-\phi}(z) \equiv 0$), and $\Phi_{1}(\cdot)$ is a particular solution of the nonhomogeneous problem (17) of the form

$$
\Phi_{1}(z) = \frac{Z_{\theta_{1}}(z)}{2\pi i} \int_{\Gamma} \frac{g(\xi)}{Z_{\theta_{1}}^{+}(\xi)} \frac{d\xi}{\xi - z}, \quad z \notin \Gamma;
$$

(2) for $m-\phi < -1$, the nonhomogeneous problem (17) is solvable only when the right-hand side $g(\cdot)$ satisfies the orthogonality conditions

$$
\int_{\Gamma} \frac{g(\xi)}{Z_{\theta_{1}}^{+}(\xi)} \xi^{k-1}d\xi = 0, \quad k \in \overline{1,\phi - m - 1},
$$

and the unique solution $\Phi(z) = \Phi_{1}(z)$ is defined by (18).

We call the integer $\phi(G) = m - \phi + 1 = m - \sum_{k=0}^{l} \left[ \frac{-\alpha_k}{p} + \frac{1}{p} \right] + 1$ an index of the problem (7) in the classes $E_{p,\rho}(D^+) \times_{m} E_{p,\rho}(D^-)$.

Thus, for $\phi(G) \geq 0$ the problem (7) is always solvable, while for $\phi(G) < 0$ it is only solvable when the orthogonality conditions hold ($-\phi(G)$).

Let us simplify the formulation of Statement 3. From (15) we have

$$
0 < \frac{\beta_1}{p} + \frac{1}{p} - n_1 < 1 \Rightarrow n_1 = \left[ \frac{\beta_1}{p} + \frac{1}{p} \right],
$$

$$
0 < \frac{\beta_k}{p} + \frac{1}{p} - (n_k - n_{k-1}) < 1 \Rightarrow n_k - n_{k-1} = \left[ \frac{\beta_k}{p} + \frac{1}{p} \right],
$$

$$
\Rightarrow n_2 = \left[ \frac{\beta_2}{p} + \frac{1}{p} \right] + n_1 = \left[ \frac{\beta_1}{p} + \frac{1}{p} \right] + \left[ \frac{\beta_2}{p} + \frac{1}{p} \right], \ldots,
$$

$$
n_l = \sum_{k=1}^{l} \left[ \frac{\beta_k}{p} + \frac{1}{p} \right].
$$

Then from (16) it follows that

$$
n_l = - \left[ \frac{\beta_0}{p} + \frac{1}{p} \right] \Rightarrow \sum_{k=0}^{l} \left[ \frac{\beta_k}{p} + \frac{1}{p} \right] = 0.$$
Therefore, Statement 3 can be restated as follows.

**Statement 5.** Let the coefficient $G(\cdot)$ and the curve $\Gamma$ satisfy the conditions (i)–(iii), let the weight $\rho(\cdot)$ be defined by (11), and let $\{\beta_k\}_0^I$ be defined by (13). Let also the conditions

$$\left\{ \frac{\beta_k}{p} \right\} \cap \mathbb{Z}_p = \emptyset; \quad \alpha_k < \frac{p}{q}, \quad k \in \mathbb{N},$$

hold. If $\sum_{k=0}^I \left[ \frac{\beta_k}{p} + \frac{1}{p} \right] = 0$, then the assertions 1) and 2) of Statement 3 are true with regard to the solvability of the problem (7) in the classes $E_{p,\rho}(D^+) \times mE_{p,\rho}(D^-)$.

Now let us consider the more general case. By Statement 4 we have

$$-\frac{1}{p} < \frac{\beta_0}{p} < \frac{1}{q} \Rightarrow 0 < \frac{\beta_0}{p} + n_l + \phi + \frac{1}{p} < 1$$

$$\Rightarrow n_l + \phi = - \left[ \frac{\beta_0}{p} + \frac{1}{p} \right] \Rightarrow \phi = - \left[ \frac{\beta_0}{p} + \frac{1}{p} \right] - n_l = - \sum_{k=0}^I \left[ \frac{\beta_k}{p} + \frac{1}{p} \right].$$

The solution of the boundary value problem (7) is expressed in terms of the solutions of the boundary value problem (17) by the formula

$$F(z) = \begin{cases} \Phi(z), & z \in D^+, \\ \omega(z) \Phi(z), & z \in D^- \end{cases}$$

Taking into account these relations, from Statement 4 we obtain the following theorem.

**Theorem 4.** Let the coefficient $G(\cdot)$ and the curve $\Gamma$ satisfy the conditions (i)–(iii), and let the weight function $\rho(\cdot)$ be defined by (11). Assume that the following conditions hold:

$$\{\beta_k\}_0^I \cap \mathbb{Z}_p = \emptyset; \quad \alpha_k < \frac{p}{q}, \quad k \in \mathbb{N},$$

where $\beta_k$, $k \in \mathbb{N}$, are defined by (13). Let

$$\phi(G) = m - \phi + 1 = m - \sum_{k=0}^I \left[ \frac{\beta_k}{p} + \frac{1}{p} \right] + 1.$$ 

Then the following assertions are true with regard to the solvability of the problem (7) in the classes $E_{p,\rho}(D^+) \times mE_{p,\rho}(D^-)$:

1. for $\phi(G) = m - \phi + 1 \geq 0$, the problem (7) has a general solution of the form

$$F(z) = F_0(z) P_{\phi(G)-1}(z) + F_1(z),$$
\[ F_0(z) = \begin{cases} Z_{\theta_1}(z), & z \in D^+, \\ (z - z_0)\phi Z_{\theta_1}(z), & z \in D^-, \end{cases} \]

where \( Z_{\theta_1}(\cdot) \) is a canonical solution of the homogeneous Riemann problem with the coefficient \( G_1(\cdot) \), \( P_{\phi(G) - 1}(\cdot) \) is an arbitrary polynomial of degree \( k \leq \phi(G) - 1 \) (for \( \phi(G) = 0 \) we assume \( P_{\phi(G) - 1}(z) \equiv 0 \)), and \( F_1(\cdot) \) is a particular solution of the nonhomogeneous problem (7) of the form

\[ F_1(z) = \begin{cases} \Phi_1(z), & z \in D^+, \\ (z - z_0)\phi \Phi_1(z), & z \in D^-, \end{cases} \]

where the function \( \Phi_1(\cdot) \) is defined by the Cauchy type integral (18).

Consider the case where the argument \( \theta(\cdot) \) of the coefficient \( G(\cdot) \) is a Hölder function on \( \Gamma \). Then the discontinuity points of the function \( \theta(\cdot) \) do not exist and, obviously, the corresponding jumps are equal to zero. Thus, by agreed notations, we have \( \{\sigma_k\}_1 \equiv \{t_k\}_1 \), and \( \{\tilde{\beta}_k\}'s, \) corresponding to the argument \( \tilde{\theta}(\cdot), \) are equal to

\[ \tilde{\beta}_k = -\frac{p}{2\pi} \tilde{h}_k + \alpha_k \Rightarrow -\frac{\beta_k}{p} = -\frac{\alpha_k}{p} + n_k - n_{k-1}, \quad k \in \Gamma, m_0, \quad n_0 = 0. \]

From (15) we obtain

\[ -\frac{1}{p} < \frac{\alpha_k}{p} + n_{k-1} - n_k < \frac{1}{q}, \quad \frac{\alpha_k}{p} < \frac{1}{q}, \quad k = \Gamma, m_0, \quad n_0 = 0. \]

It follows that if there exists \( k_0 \in \Gamma, m_0 \) such that \( n_{k_0-1} - n_{k_0} < 0 \), i.e., \( n_{k_0-1} - n_{k_0} \leq -1 \), then

\[ \frac{\alpha_{k_0}}{p} \geq -\frac{1}{p} - (n_{k_0-1} - n_{k_0}) - \frac{1}{p} + 1 = \frac{1}{q}, \]

which contradicts the condition \( \frac{\alpha_{k_0}}{p} < \frac{1}{q} \). Consequently

\[ n_{k-1} - n_k \geq 0, \quad k \in \Gamma, m_0 \Rightarrow n_k \leq n_{k-1} \Rightarrow n_k \leq 0, \quad k \in \Gamma, m_0, \]

because \( n_0 = 0 \). Then \( n_l \leq 0 \). If \( n_l \leq -1 \), then from (16) we obtain

\[ -\frac{1}{p} < \frac{\beta_0}{p} + n_l < \frac{1}{q}, \quad \frac{\alpha_0}{p} < \frac{1}{q}. \]
where $\beta_0 = \alpha_0$. Again we have $\frac{\alpha_n}{p} > -\frac{1}{p} - n_l \geq \frac{1}{q}$, and this contradicts the condition $\frac{\alpha_n}{p} < \frac{1}{q}$. So we obtain $n_k = 0$ for all $k \in 1, m_0$, and, consequently

$$-\frac{1}{p} < \frac{\alpha_k}{p} < \frac{1}{q}, \ k \in 1, m_0,$$

i.e., the conditions (16) become the Muckenhoupt condition with regard to the weight function $\rho (\cdot)$. So the following statement is true.

**Statement 6.** Let the argument $\theta (\cdot)$ of the coefficient $G (\cdot)$ be a Hölder function on $\Gamma$. Then the conditions (16) of Statement 3 hold if and only if the weight $\rho (\cdot)$ satisfies the Muckenhoupt condition, i.e., $\rho (\cdot) \in A_p (\Gamma), \ 1 < p < +\infty$.

### 3.2. General weight.

Before turning to the case of a general weight, let us define the class of weights we need. So, let $\{\xi_k\}_1^n \subset \Gamma$ be some finite subset of $\Gamma$. Denote by $A_p (\{\xi_k\}_1^n ; \Gamma)$ the set of weights $\rho (\cdot)$ for which there exists a set of integers $\{n_k\}_1^n \subset \mathbb{Z}$ such that $\tilde{\rho} (\cdot) \in A_p (\Gamma)$, where

$$\tilde{\rho} (\xi) = \prod_{k=1}^n |\xi - \xi_k|^{-n_k} \rho (\xi), \ \xi \in \Gamma.$$

The following lemma is true.

**Lemma 3.** The set of integers $\{n_k\}_1^n \subset \mathbb{Z}$ in the definition of the class $A_p (\{\xi_k\}_1^n ; \Gamma)$ with $1 < p < +\infty$ is defined uniquely.

**Proof.** First we consider the case where the set $\{\xi_k\}_1^n$ consists of one point, i.e., $n = 1$. Assume the contrary, i.e., there exist $n_1, n_2 \in \mathbb{Z}$ such that

$$\rho_k (\xi) = |\xi - \xi_1|^{-p n_k} \rho (\xi) \in A_p (\Gamma), \ k = 1, 2.$$

Without loss of generality, we will assume that $n_2 = n_1 + n_0$, where $n_0 \in \mathbb{N}$, i.e., $n_0 \geq 1$. We have

$$\rho_2 (\xi) = \rho_1 (\xi) |\xi - \xi_1|^{-p n_0} \Rightarrow |\xi - \xi_1|^{-n_0} = \rho_2^\frac{1}{p} (\xi) \rho_1^{-\frac{1}{p}} (\xi).$$

Hence, applying Hölder’s inequality, we obtain

$$\int_{\Gamma} |\xi - \xi_1|^{-n_0} |d\xi| \leq \left( \int_{\Gamma} \rho_2 (\xi) |d\xi| \right)^{\frac{1}{p}} \left( \int_{\Gamma} \rho_1^\frac{2}{p} (\xi) |d\xi| \right)^{\frac{1}{q}}, \ \frac{1}{p} + \frac{1}{q} = 1. \quad (20)$$

From $\rho_k (\cdot) \in A_p (\Gamma), \ 1 < p < +\infty, \ k = 1, 2$, it follows that $\rho_2 (\cdot) \in L_1 (\Gamma), \ \rho_1^\frac{2}{p} (\cdot) \in L_1 (\Gamma)$. Then from (20) we obtain $|\xi - \xi_1|^{-n_0} \in L_1 (\Gamma)$, which contradicts the condition $n_0 \geq 1$. The case $n = 1$ is proved.

The general case is reduced to this case by using the relation

$$\prod_{k=1}^n |\xi - \xi_1|^{-p n_k} \rho (\xi) \in A_p (\Gamma), \ \xi \in 1, n,$$
where $\Gamma_k \subset \Gamma$, $k \in \overline{1,n}$, is a part of the curve $\Gamma$, which contains only $\xi_k$ and no other point $\xi_i$, $i \neq k$, and, besides, $\xi_k$ is an internal point of $\Gamma_k$. \hfill \Box$

As before, we will assume that $0 = \sigma_0 < \sigma_1 < \ldots < \sigma_l < S$, and let

$$\tilde{\theta} (z (s)) = \begin{cases} \theta (z (s)), & 0 < s < \sigma_1, \\ \theta (z (s)) + 2\pi \tilde{n}_1, & \sigma_1 < s < \sigma_2, \\ \vdots \\ \theta (z (s)) + 2\pi \tilde{n}_l, & \sigma_l < s < S, \end{cases}$$

(21)

where $\{\tilde{n}_k\}_l \subset \mathbb{Z}$ are some integers. Let

$$\tilde{G} (z (s)) = |G (z (s))| e^{i\phi(z(s))}, \quad 0 < s < S,$$

and consider the Riemann boundary value problem

$$F^+ (z (s)) - \tilde{G} (z (s)) F^- (z (s)) = g (z (s)), \quad s \in (0, S),$$

(22)

with the coefficient $\tilde{G} (\cdot)$. Let $\xi_k = (\sigma_k), \quad k \in \overline{0,l}$. Assume that $\nu (\cdot) \in A_p \left( \{\xi_k\}_0^l : \Gamma \right)$. Then it follows from Lemma 3 that there exist $\{n_k\}_1 \subset \mathbb{Z}$ such that

$$\prod_{k=0}^l \left| z (\cdot) - \xi_k \right|^{-\nu (\cdot)} \nu (\cdot) \in A_p (\Gamma).$$

Let us find the jumps of the functions $\tilde{\theta} (\cdot)$ at the points $\xi_k$. We have

$$\tilde{h}_1 = \tilde{\theta} (\sigma_1 + 0) - \tilde{\theta} (\sigma_1 - 0) = h (\sigma_1) + 2\pi \tilde{n}_1;$$

$$\tilde{h}_k = h (\sigma_k) + 2\pi (\tilde{n}_k - \tilde{n}_{k-1}), \quad k \in \overline{2,l};$$

$$\tilde{h}_0 = \tilde{\theta} (S - 0) - \tilde{\theta} (0) = h (\sigma_0) - 2\pi \tilde{n}_1 = h_0 - 2\pi \tilde{n}_1.$$

Similarly to the previous case, the weight function

$$\tilde{\nu} (s) = \tilde{\sigma}^p (s) \rho (z (s))$$

corresponds to the problem (22), where

$$\tilde{\sigma} (s) = |z (0) - z (s)|^{-\tilde{n}_0} \prod_{0 < s_k < S} |z (s_k) - z (s)|^{-\tilde{n}_k \over \pi}$$

$$= |z (s) - \xi_0|^{-\tilde{n}_0 \over \pi} \prod_{k=1}^l |z (s) - \xi_k|^{-\tilde{n}_k \over \pi} |z (s) - \xi_k|^{-\tilde{n}_k + \tilde{n}_{k-1}}$$

$$= \sigma (s) |z (s) - \xi_0|^{-\tilde{n}_0} \prod_{k=1}^l |z (s) - \xi_k|^{-\tilde{n}_k + \tilde{n}_{k-1}}.$$
with \( \tilde{n}_0 = 0 \). Consequently
\[
\tilde{\nu}(s) = \nu(s) |z(s) - \xi_0|^{\tilde{m}_1} \prod_{k=1}^{l} |z(s) - \xi_k|^{-p(\tilde{n}_k - \tilde{n}_{k-1})}.
\]

Now let \( \tilde{n}_1 = n_1, \tilde{n}_k - \tilde{n}_{k-1} = n_k, k \in \mathbb{Z} \). It is absolutely clear that if \( \tilde{n}_l = -n_0 \), then \( \tilde{\nu}(\cdot) \in A_p(\Gamma) \). Therefore, applying Theorem 3 to the problem (22), we obtain the following corollary.

**Corollary 2.** Let the coefficient \( G(\cdot) \) and the curve \( \Gamma \) satisfy the conditions (i)–(iii). Assume that \( \arg G(\cdot) \) is a piecewise Hölder function on \( \Gamma \), the weight function \( \nu(\cdot) \) is defined by (8) belongs to the class \( A_p \left( \{ \xi_k \}_{0}^{l}; \Gamma \right) \), \( 1 < p < +\infty \), and \( \{n_k\}_{0}^{l} \subset \mathbb{Z} \) are the corresponding integers. We find the integer \( \tilde{n}_l \) from the relations
\[
\tilde{n}_k = n_k + \tilde{n}_{k-1}, \quad \tilde{n}_0 = 0.
\]
If \( \tilde{n}_l = -n_0 \) and \( p^{-\frac{2}{p}} (\cdot) \in L_1(\Gamma) \), then the assertions 1) and 2) of Theorem 3 are true with regard to the solvability of the problem (7) in the classes \( E_{p, \rho}(D^+) \times mE_{p, \rho}(D^-) \).

Now we consider the general case, i.e., the case where the condition \( \tilde{n}_l = -n_0 \) may in general not hold, with \( \tilde{n}_l \) defined from (23). Let \( z_0 \in D^+ \) be an arbitrary fixed point. Consider the following analytic function in \( D^- \):
\[
\omega(z) = (z - z_0)^\phi, \quad z \in D^-,
\]
where \( \phi \in \mathbb{Z} \) is some integer. Following the previous case (i.e., the case of power weight), we have
\[
\omega^-(\xi) = (\xi - z_0)^\phi, \quad \gamma(\xi) = \arg \omega^-(\xi), \quad \xi \in \Gamma.
\]
Let
\[
G_1(\xi) = \hat{G}(\xi) \omega^-(\xi), \quad \xi \in \Gamma.
\]
Consequently
\[
\theta_1(\xi) = \arg G_1(\xi) = \hat{\theta}(\xi) + \gamma(\xi), \quad \xi \in \Gamma.
\]
The discontinuity points and the jumps of the function \( \theta_1(z(\cdot)) \) coincide with the discontinuity points and the jumps of the function \( \hat{\theta}(z(\cdot)) \) on \((0, S)\). The jump \( h_0(\theta_1) \) of the function \( \theta_1(\cdot) \) at the point \( \xi = a \) is equal to
\[
h_0(\theta_1) = \theta_1(z(+0)) - \theta_1(z(S-0))
= \hat{\theta}(z(+0)) - \hat{\theta}(z(S-0)) + \gamma(z(+0)) - \gamma(z(S-0))
= \hat{h}_0 - 2\pi\phi = h(\sigma_0) - 2\pi\tilde{n}_l - 2\pi\phi.
\]
As before, the weight
\[
\nu_1(s) = \sigma_1 p(s)\rho(z(s))
\]
corresponds to the Riemann problem with the coefficient $G_1(\cdot)$, where
\[
\tilde{\sigma}_1(s) = |z(0) - z(s)|^{-\frac{\nu_0(\theta_1)}{2\pi}} \prod_{0 < s_k < S} |z(s_k) - z(s)|^{-\frac{\nu_k(\theta_1)}{2\pi}}
\]
\[
= |z(s) - \xi_0|^{-\frac{\nu_0}{2\pi}} |z(s) - \xi_0|^\tilde{n}_l + \phi \prod_{k=1}^l |z(s) - \xi_k|^{-\frac{\nu_k}{2\pi}} |z(s) - \xi_k|^{-\tilde{n}_k + \tilde{n}_{k-1}}
\]
\[
= \sigma(s) |z(s) - \xi_0|^\tilde{n}_l + \phi \prod_{k=1}^l |z(s) - \xi_k|^{-\tilde{n}_k + \tilde{n}_{k-1}},
\]
with $\tilde{n}_0 = 0$. Then
\[
\nu_1(s) = \nu(s) |z(s) - \xi_0|^{p(\tilde{n}_l + \phi)} \prod_{k=1}^l |z(s) - \xi_k|^{-p(\tilde{n}_k - \tilde{n}_{k-1})}.
\]
We find the integer $\tilde{n}_l$ from (23) and set
$$\tilde{n}_l + \phi = -n_0 \Rightarrow \phi = -n_0 - \tilde{n}_l.$$ Then we obtain that the coefficient $G_1(\cdot)$ satisfies all the conditions of Theorem 3. Transform the problem (7) as follows:
\[
F^+ (\xi) - G(\xi) \omega^-(\xi) \frac{F^- (\xi)}{\omega^-(\xi)} = g(\xi), \quad \xi \in \Gamma,
\]
$$\Phi^+ (\xi) - G_1(\xi) \Phi^- (\xi) = g(\xi), \quad \xi \in \Gamma,$$
where
$$\Phi(z) = \begin{cases} F(z), & z \in D^+, \\ \frac{F(z)}{\omega(z)}, & z \in D^- \end{cases}.$$ It is absolutely clear that
$$\Phi^- (\xi) = F^- (\xi) \omega^{-1}(\xi), \quad \xi \in \Gamma.$$ Moreover, if $F(z)$ has an expansion in the neighborhood of $z = \infty$ of the form
\[
F(z) = \sum_{k=-\infty}^m a_k z^k, a_m \neq 0, z \to \infty,
\]
then $\Phi(z)$ has an expansion of the form
\[
\Phi(z) = \sum_{k=-\phi}^{m-\phi} b_k z^k, b_{m-\phi} \neq 0, \ z \to \infty,
\]
and vice versa. In view of
$$\omega(\xi) \sim \text{const}, \quad \xi \in \Gamma,$$
from these relations we obtain that the function $F(\cdot)$ belongs to the class $mE_{p,\rho}(D^-)$ if and only if the function $\Phi(\cdot)$ belongs to the class $m_{-\phi}E_{p,\rho}(D^-)$, i.e., $F(\cdot) \in mE_{p,\rho}(D^-) \Leftrightarrow \Phi(\cdot) \in m_{-\phi}E_{p,\rho}(D^-)$. Thus, the solvability of the problem (7) in the classes $E_{p,\rho}(D^+) \times mE_{p,\rho}(D^-)$ is equivalent to the solvability of the problem (24) in the classes $E_{p,\rho}(D^+) \times m_{-\phi}E_{p,\rho}(D^-)$. Applying Theorem 3 to the problem (24), we obtain the following statement.

Statement 7. Let the coefficient $G(\cdot)$ and the curve $\Gamma$ satisfy the conditions (i)--(iii), and let $\arg G(\cdot)$ be a piecewise Hölder function on $\Gamma$. Assume that the weight function $\nu(\cdot)$ defined by (8) belongs to the class $A_p \left(\left\{\xi_k\right\}_{0}^{l}; \Gamma\right)$, $\left\{n_k\right\}_{0}^{l} \subset \mathbb{Z}$ are the corresponding integers, $\phi = -\sum_{k=0}^{l} n_k$, and $\rho^{-\frac{2}{\nu}}(\cdot) \in L_1(\Gamma)$. Then the following assertions are true with regard to the solvability of the problem (24) in the classes $E_{p,\rho}(D^+) \times m_{-\phi}E_{p,\rho}(D^-)$:

1. for $m - \phi \geq -1$, the problem (24) has a general solution of the form

$$\Phi(z) = Z_{\theta_1}(z) P_{m-\phi}(z) + \Phi_1(z),$$

where $Z_{\theta_1}(\cdot)$ is a canonical solution of the homogeneous problem with the coefficient $G_1(\cdot)$, $P_{m-\phi}(\cdot)$ is an arbitrary polynomial of degree $k \leq m - \phi$ (for $m - \phi = -1$ we assume $P_{m-\phi}(z) \equiv 0$), and $\Phi_1(\cdot)$ is a particular solution of the form

$$\Phi_1(z) = \frac{Z_{\theta_1}(z)}{2\pi i} \int_{\Gamma} \frac{g(\xi)}{Z_{\theta_1}^+(\xi) \xi - z} \, d\xi, \quad z \notin \Gamma; \tag{25}$$

2. for $m - \phi < -1$, the nonhomogeneous problem (24) is solvable only when the right-hand side $g(\cdot)$ satisfies the orthogonality conditions

$$\int_{\Gamma} \frac{g(\xi)}{Z_{\theta_1}^+(\xi)} \xi^{k-1} d\xi = 0, \quad k \in \overline{1, \phi - m - 1}, \tag{26}$$

and the unique solution $\Phi_1(\cdot)$ is defined by (25).

Now back to the problem (7). Considering the relationship between the problems (7) and (24), we have

$$F(z) = \begin{cases} \Phi(z), & z \in D^+, \\ \omega(z) \Phi(z), & z \in D^- . \end{cases}$$

So the following theorem is true.

Theorem 5. Let $G(\cdot)$, $\Gamma$, $\arg G(\cdot)$, $\nu(\cdot)$, $\phi$, and $\rho^{-\frac{2}{\nu}}$ be the same as in Statement 7. Then the following assertions are true with regard to the solvability of the problem (7) in the classes $E_{p,\rho}(D^+) \times mE_{p,\rho}(D^-)$:

1. for $m - \phi \geq -1$, the problem (24) has a general solution of the form

$$F_0(z) = \begin{cases} Z_{\theta_1}(z) P_{m-\phi}(z) + \Phi_1(z), & z \in D^+, \\ (z - z_0)^{\phi} \big(Z_{\theta_1}(z) P_{m-\phi}(z) + \Phi_1(z)\big), & z \in D^- , \end{cases}$$
where $Z_{\theta_1}(\cdot)$ is a canonical solution of homogeneous problem

$$F^+(\xi) - G_1(\xi) F^-(\xi) = 0, \quad \xi \in \Gamma,$$

$G_1(\cdot)$ is a coefficient, $P_{m-\phi}(\cdot)$ is an arbitrary polynomial of degree $k \leq m - \phi$ (for $m - \phi = -1$ we assume $P_{m-\phi}(z) \equiv 0$), and $\Phi_1(\cdot)$ is defined by (25);

(2) for $m - \phi < -1$, the nonhomogeneous problem (7) is solvable only when the right-hand side $g(\cdot)$ satisfies the orthogonality conditions (26), and the unique solution $\Phi_1(\cdot)$ is defined by

$$\Phi_1(z) = \begin{cases} \Phi_1(z), & z \in D^+, \\ (z - z_0)^\phi \Phi_1(z), & z \in D^-, \end{cases}$$

where $\Phi_1(\cdot)$ is defined by (25).

The number $\phi(G) = m - \phi + 1 = m - \sum_{k=0}^I n_k + 1$, where the integers \{n_k\}_0 are defined from the condition $\nu(\cdot) \in A_p \left( \{\xi_k\}_0^I ; \Gamma \right)$, is called an index of the problem (7) in the classes $E_{p,\rho}(D^+) \times mE_{p,\rho}(D^-)$.

Thus, for $\phi(G) \geq 0$ the problem (7) is always solvable, for $\phi(G) = 0$ it has a unique solution and it is solvable for all $g(\cdot) \in L_{p,\rho}(\Gamma)$; for $\phi(G) < 0$ it is solvable if the orthogonality conditions hold ($-\phi(G)$).

Assume that the argument $\theta(\cdot)$ of the coefficient $G(\cdot)$ is a Hölder function on $\Gamma$. In this case, the discontinuity points and the jumps of the function $\theta(\cdot)$ do not exist and, therefore, $\sigma_k = t_k, k \in \Gamma, m_0$. Let us consider the weight function

$$\tilde{\nu}(s) = \tilde{\sigma}^p(s) \rho(z(s)),$$

which corresponds to the function $\tilde{\theta}(\cdot)$ defined by (21), where

$$\tilde{\sigma}(s) = |z(s) - \xi_0|^\tilde{n}_0 \prod_{k=1}^I |z(s) - \xi_k|^{-\tilde{n}_k + \tilde{n}_k - 1}, \quad \tilde{n}_0 = 0.$$

Denote by $\Gamma_k, k \in 0, m_0$ the connected part of $\Gamma$, for which $O_\delta(\xi_k) \subset \Gamma_k, \xi_i \notin \Gamma_k$ for any $i \neq k$, where $O_\delta(\xi_k) = \{\xi \in \Gamma : |\xi - \xi_k| < \delta\}$, and $\Gamma_k$ is a closure of $\Gamma_k$. Consequently

$$\tilde{\sigma}(s) = \tilde{\nu}^{\frac{1}{p}}(s) \rho \tilde{\nu}^{-\frac{1}{p}}(z(s)), \quad 0 < s < S.$$

Assume that all the conditions of Theorem 5 hold. Then

$$\tilde{\nu}(\cdot) \in A_p(\Gamma) \land \rho^{-\frac{p}{2}}(\cdot) \in L_1(\Gamma)$$

and so

$$\tilde{\nu}(\cdot) \in A_p(\Gamma_k), \quad k \in 0, m_0.$$

As

$$\tilde{\sigma}(\xi) \sim |\xi - \xi_k|^{-\tilde{n}_k - 1 - \tilde{n}_k}, \tilde{n}_0 = 0, \quad \xi \in \Gamma_k, k = \Gamma, m_0;$$

$$\tilde{\sigma}(\xi) \sim |\xi - \xi_0|^{\tilde{n}_0}, \quad \xi \in \Gamma_0,$$
it is clear that
\[ |z(s) - \xi_k| \sim \tilde{\nu}^{\frac{1}{p}}(s) \rho^{\frac{1}{p}}(z(s)), \quad z(s) \in \Gamma_k, \quad \tilde{n}_0 = 0, \quad k \in \overline{1,m_0}; \]
\[ |z(s) - \xi_0| \sim \tilde{\nu}^{\frac{1}{p}}(s) \rho^{\frac{1}{p}}(z(s)), \quad z(s) \in \Gamma_0. \]
If, for some \( k_0 \in \overline{0,m_0}, \)
\[ \tilde{n}_{k_0 - 1} - \tilde{n}_{k_0} \leq -1 \quad (k_0 = 0 \Rightarrow \tilde{n}_{m_0} \leq -1), \]
than from the previous relations we obtain
\[ \int_{\Gamma_{k_0}} |z(s) - \xi_{k_0}|^{\gamma_{k_0}} |dz(s)| \]
\[ \leq C \left( \int_{\Gamma_{k_0}} \tilde{\nu}(s) |dz(s)| \right)^{\frac{1}{p}} \left( \int_{\Gamma_{k_0}} \rho^{-\frac{q}{p}}(z(s)) |dz(s)| \right)^{\frac{1}{q}}, \quad (29) \]
where
\[ \gamma_k = \begin{cases} \tilde{n}_{k-1} - \tilde{n}_k, & k \in \overline{1,m_0}, \\ \tilde{n}_{m_0}, & k = 0. \end{cases} \]
Hence, in view of (27) and (28), we have \( |\xi - \xi_{k_0}|^{\gamma_{k_0}} \in L_1(\Gamma_{k_0}), \) which contradicts the condition \( \gamma_{k_0} \leq -1. \) Consequently, \( \gamma_k \geq 0 \) for all \( k \in \overline{0,m_0}. \)
We have
\[ \tilde{n}_{k-1} - \tilde{n}_k \geq 0, \quad k \in \overline{1,m_0} \Rightarrow \tilde{n}_k \leq \tilde{n}_{k-1}, \quad \tilde{n}_0 = 0, \quad k \in \overline{1,m_0}. \]
It follows directly that if for some \( k_0 \in \overline{1,m_0-1} \) the relation \( \tilde{n}_{k_0} \leq -1 \) holds, then \( \tilde{n}_{m_0} \leq -1. \) As a result, from (29) when \( k_0 = m_0 \) we arrive at a contradiction. It follows that, in the case considered, all conditions of Theorem 5 can be satisfied only when
\[ \tilde{n}_k = 0, \quad k \in \overline{0,m_0} \Rightarrow \tilde{\nu}(s) = \rho(z(s)) = \rho(\cdot) \in A_p(\Gamma). \]
So, the following statement is valid.

**Statement 8.** Let the argument \( \theta(\cdot) \) of the coefficient \( G(\cdot) \) be a Hölder function on \( \Gamma. \) Then the conditions of Theorem 5 are satisfied, i.e., \( \nu(\cdot) \in A_p(\{t_k\}_{0}^{m_0};\Gamma) \), \( 1 < p < +\infty \), if and only if \( \rho(\cdot) \in A_p(\Gamma) \).

**Remark 1.** It follows from the results of Statements 6 and 7, and the expression \( \nu(s) = \sigma^p(s)\rho(z(s)) \) for the weight function \( \nu(\cdot) \) that, when \( \arg G(\cdot) \) has discontinuities, then for solvability of corresponding problems, the weight \( \rho(\cdot) \) may in general not satisfy the Muckenhoupt condition.
