#### Abstract

The goal of the present study was to investigate correlation between the body surface area created by various formulas and other anthropometric measurements.

The subjects of the present investigation were 17-year-old conscripts of the town of Tartu and Tartu County.

In all of them height, weight, 33 anthropometric variables and 12 skinfolds were measured. The measurements were made according to the recommendations of Martin (Knussmann, 1988).

The body surface area was calculated by five different formulas. There was significant correlation between the body surface area and the other anthropometric variables.

Key words: correlation analysis, anthropometrical variables, body surface area.

## INTRODUCTION

In the second half of the $20^{\text {th }}$ century anthropologists from Estonia Tiik [1] and Kaarma [2, 3] in their studies were interested in applying the correlation analysis in physical anthropology. It was shown that there is significant correlation between the weight and the other anthropometrical variables and also between the height and the others anthropometrical variables [1, 2]. In this situation Kaarma made an
essential novelty corollary and named the height and weight as leading variables among all the investigated anthropometrical variables. In the studies of Kaarma also the body surface are was used, but there we did not find any investigations of the correlation between the body surface area and the other anthropometrical variables.

The goal of the present study was to investigate the correlation between the body surface area and the others anthropometrical variables.

The second goal of the study was to investigate the difference of the mean results of the body surface area calculated by various formulas in 17 -year-old conscripts.

## MATERIAL AND METHODS

The subjects of the present study were 739 seventeen-year-old conscripts from the town of Tartu and the Tartu County. Measurements were taken of each subject in all 47 anthropometric variables. Total body weight was measured with Soehnle digital scale with precision of 0.05 kg . During the anthropometric investigation the rules of Martin (Knussmann 1988) [4] were followed. Height measurements included eight variables: height, suprasternale height, processus xiphoideus height, umbilical height, symphyseal height, acromiale height and height of anterior superior iliac spine.

Breadth and depth measurements were as follows: biacromiale breadth, chest breadth and depth, waist breadth, bicristal diameter, elbow breath, wrist, femur and bimalleolar breadth. Abdomen depth was measured between umbilicus and processus spinosus columnae vertebralis lumbalis on horizontal plane.

Circumferences were as follows: chest, waist, neck, hip, arm relaxed and arm flexed and tensed, forearm, wrist, upper thigh, calf and minimum ancle circumference. Pelvis circumference was measured laterally at the level of the iliac crests. Midthigh was measured in the middle of distance between spina iliaca anterior superior and upper crest of patella. Head circumference was measured superior to the eyebrow line and encompassing the occipital protuberance. Skinfolds were measured as follows: chin, chest, midaxillary, suprailiac, supraspinale (the fold was picked up three-four centimeters above the anterior superior iliac spine on a diagonal line going downwards and inwards), subscapular, abdominal, biceps and triceps, femoral, calf and dorsal
surface of right hand. In skinfolds measuring recommendations of Lohman et al. [5] and Heyward and Stolarzcyk [6] were also followed.

All anthropometrical variables were measured on the right side.
Sternal length was calculated as suprasternale height minus processus xiphoideus height.

Abdominal length was derived as processus xiphoideus height minus symphyseal height.

Trunk length was calculated as suprasternale height minus symphyseal height. Upper limb length was calculated as acromiale height minus dactylion height.

Lower limb length was calculated as sum of the heights of anterior superior iliac spine and symphyseal height

For predicting the body surface area several different formulas are recommended.

In 1916 Du Bois and Du Bois [7] measured in nine individuals the body surface area directly using molds. From these results they generated a formula to predict body surface are using height and weight alone.

We used the following variant of the formula BSA $\left(\mathrm{m}^{2}\right)=0.007184$ x height $(\mathrm{cm})^{0.725} \mathrm{x}$ weight $(\mathrm{kg})^{0.425}$.

The second formula was generated by Haycock [8]: BSA $\left(\mathrm{m}^{2}\right)=$ 0.024265 x height $(\mathrm{cm})^{0.3964} \mathrm{x}$ weight $(\mathrm{kg})^{0.5378}$.

The third formula was produced by Gehan and George [9]: BSA ( $\mathrm{m}^{2}$ ) $=0.0235 \mathrm{x}$ height $(\mathrm{cm})^{0.42246} \mathrm{x}$ weight $(\mathrm{kg})^{0.51456}$.

The fourth formula was calculated by Boyd [10]: BSA $\left(\mathrm{m}^{2}\right)=$ 0.0003207 x height $(\mathrm{cm})^{0.3} \mathrm{x}$ weight (grams) ${ }^{(0.7285-(0.0188 \times \operatorname{LOG}(\text { grams }))}$.

The fifth formula was recommended by Mosteller [11, 12]: BSA $\left(\mathrm{m}^{2}\right)=([\text { Height }(\mathrm{cm}) \times \text { Weight }(\mathrm{kg})] / 3600)^{0.5}$.

The data were processed by the SAS for Windows version 6.12 software. The level of significance was set at $\mathrm{p}<0.05$.

## RESULTS

The results are presented in Tables 1 and 2.

Table 1. Correlations between anthropometrical variables data and body surface area calculated by five authors formulas of 17 -year-old conscripts

| No | Variable | Dubois <br> and <br> Dubois | Hay- <br> cock | Gehan and <br> George | Boyd | Mos- <br> teller |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: |
| 1. | weight (kg) | 956 | 987 | 985 | 991 | 980 |

|  | skinfolds $(\mathrm{mm})$ |  |  |  |  |  |
| 31. | chin skinfold | 510 | 570 | 564 | 580 | 554 |
| 32. | chest skinfold | 598 | 661 | 654 | 670 | 644 |
| 33. | midaxillary skinfold | 647 | 717 | 710 | 728 | 698 |
| 34. | suprailiac skinfold | 645 | 737 | 731 | 746 | 720 |
| 35. | supraspinale skinfold | 614 | 678 | 672 | 688 | 661 |
| 36. | abdominal skinfold | 653 | 718 | 712 | 728 | 700 |
| 37. | subscapular skinfold | 652 | 718 | 711 | 728 | 700 |
| 38. | biceps skinfold | 510 | 567 | 561 | 576 | 551 |
| 39. | triceps skinfold | 638 | 698 | 692 | 708 | 681 |
| 40. | thigh skinfold | 616 | 669 | 664 | 677 | 654 |
| 41. | calf skinfold | 610 | 661 | 656 | 668 | 647 |
|  | indices |  |  |  |  |  |
| 42. | body mass index | 759 | 844 | 836 | 859 | 821 |

In Table 1 the correlations between the weight and the body surface area are given, they are very strong. The correlations between the height and the body surface area are a little weaker. All correlations are significant.

Table 2. Mean and SD of body surface area calculated by five authors formulas of 17-year-old conscripts

| No. | Formula | Mean $\pm \mathrm{SD} \mathrm{m}^{2}$ | Difference <br> significance -p |
| :--- | :--- | :---: | :---: |
| 1. | Du Bois and Du Bois | $1,866 \pm 0.16$ |  |
| 2. | by Haycock | $1.848 \pm 0.02$ | 0.396 |
| 3. | by Gehan and George | $1.837 \pm 0.17$ | 0.500 |
| 4. | by Boyd | $1.847 \pm 0.18$ | 0.499 |
| 5. | by Mosteller | $1.852 \pm 0.18$ | 0.436 |

In Table 2 the mean and SD values in $\mathrm{m}^{2}$, which are calculated by five author's formulas are given. Comparing these results, using the paired sample t -test, there was no significant difference ( $\mathrm{p}>0.05$ ).

## DISCUSSION

The present investigation showed that in the material of the 17-year-old conscripts of the town of Tartu and the Tartu County there are really the correlations between the body surface areas calculated by five different formulas and other anthropometrical variables of the body. Thus it is demonstrated, that not only the height and the weight and the body mass index, as it was shown our previous study[13], but also the body surface area calculated by height and weight is well correlated with other anthropometric variables of the body in the 17-year-old conscripts.

The body surface area is used for the adjustment of the drug dose $[14,15]$ and of the dose of dialysis in children and adolescents [16].
